```

/content/drive/MyDrive/TRIED/TP3/TRIED/TP3/data

Exercice 0 : Fonction d'activation ReLU

On va comparer la fonction d'activation sigmoïde utilisée dans les TP précédents par une fonction ReLU (Rectified Linear Unit).

- Reprendre le perceptron à une couche cachée du TP3 en utilisant une non-linéarité ReLU. Observer le nombre d'itérations (epochs) nécessaires pour atteindre la convergence de réseau.
- Reprendre le réseau convolutif du TP3 en utilisant des non-linéarités ReLU pour les couches convolutives. Observer le nombre d'itérations (epochs) nécessaires pour atteindre la convergence de réseau.

Conclure sur l'intérêt de la fonction d'activation ReLU.

- MLP, sigmoid: 49 epochs (acc=97.67)
- MLP, ReLU: 11 epochs (acc=97.81)
- CNN, sigmoid: 8 epochs (acc=98.75)
- CNN, ReLU: 5 epochs (acc=98.97)

On observe une nette amélioration en termes de convergence en passant de la sigmoïde à ReLU. Les résultats indiquent clairement que ReLU permet une convergence plus rapide

des modèles, ce qui se traduit par un nombre d'épochs plus faible nécessaire pour atteindre une performance élevée.

Transfer Learning et Fine-Tuning sur VOC2007

L'apprentissage par transfert (Transfer Learning) fait référence à l'utilisation de modèles pré-entraînés sur une tâche connexe comme point de départ pour l'entraînement sur une nouvelle tâche. Le modèle pré-entraîné fournit une bonne initialisation des poids, réduisant ainsi la quantité de données et de ressources computationnelles nécessaires pour entraîner le modèle.

L'ajustement fin (Fine-tuning) désigne le processus d'adaptation d'un modèle pré-entraîné à une nouvelle tâche en l'entraînant sur un ensemble de données plus petit pendant quelques itérations. Cela implique de mettre à jour certains ou la totalité des paramètres du modèle afin de l'optimiser pour la nouvelle tâche, tout en conservant les informations utiles acquises lors de la tâche initiale. L'objectif est d'obtenir de meilleures performances sur la nouvelle tâche que si l'on entraînait le modèle à partir de zéro.

En pratique, les réseaux de neurones convolutifs (CNNs) ne sont généralement pas entraînés à partir de zéro. Il est plus pratique d'utiliser des réseaux pré-entraînés sur de grandes bases de données comme ImageNet (qui contient environ 12 millions d'images réparties en 10 000 classes). Dans cette partie, différentes approches sont explorées, notamment l'ajustement fin et l'apprentissage par transfert, afin d'entraîner des CNNs. Nous utilisons la base de données VOC2007.

Cette base de données comprend 20 classes (parmi les macro-catégories, on trouve par exemple « Personne » ou « Véhicule »), mais avec des étiquettes dites « multi-labels ». Elle contient un ensemble d'entraînement (qui inclut des ensembles d'entraînement et de validation) composé d'environ 5 000 images, ainsi qu'un ensemble de test contenant également environ 5 000 images. Les images ont des tailles variées, avec une taille moyenne d'environ 500x300 pixels.

Exercice 1 : Modèle ResNet-50 avec Keras

Nous allons récupérer une architecture de réseau convolutif donnant des très bonnes performances sur ImageNet. On va ici s'intéresser aux réseaux ResNet [He_2016_CVPR], qui ont remporté le challenge ILSVRC en 2015. On utilisera un réseau ResNet-50 dont l'architecture détaillée peut être trouvée ici : <https://github.com/fchollet/deep-learning-models/blob/master/resnet50.py>.

Avec Keras, ce réseau est accessible avec le code suivant :

```
In [ ]: from keras.applications.resnet50 import ResNet50
model = ResNet50(include_top=True, weights='imagenet')
```

Où les poids issus de l'entraînement sur ImageNet sont directement récupérés (`weights='imagenet'`).

Exercice 2 : Extraction de « Deep Features »

Une première solution pour surmonter le manque d'exemples d'apprentissage est de se servir des réseaux pré-entraînés sur ImageNet comme extracteur de descripteurs. Nous allons appliquer le réseau ResNet50 et extraire la couche d'activations du réseau avant les 1000 classes d'ImageNet, couche de taille 2048. Ainsi, l'application du réseau sur chaque image de la base produit un vecteur de taille 2048, appelé « Deep Feature ». On peut pour cela utiliser le code suivant :

```
In [ ]: model.layers.pop()
```

```
Out[ ]: <keras.src.layers.core.dense.Dense at 0x7efd7c123a60>
```

L'utilisation de la fonction `pop()` permet de supprimer la dernière couche des (1000) classes d'ImageNet. La classe `ResNet50` du module `keras.applications.resnet50` charge un modèle de l'API fonctionnelle de Keras : <https://keras.io/getting-started/functional-api-guide/>. Pour que le dépilement de la dernière couche ait un effet sur le modèle, il faut le préciser explicitement :

```
In [ ]: from keras.models import Model
model = Model(inputs=model.input, outputs=model.layers[-2].output)
```

```
In [ ]: from keras.optimizers import SGD
```

TODO

- Vérifier l'architecture du modèle
- Le compiler (pour l'extraction futures des Deep Features). On prendra une descente de gradient stochastique comme méthode d'optimisation.

```
In [ ]: ##### VOTRE CODE ICI #####

model.summary()
```

Model: "model_1"

Chargement des données de la base. Stocker en mémoire l'ensemble des données devient impossible pour des bases de données massives. On arrive à la limite sur VOC 2007 où le tenseur d'entrée prend plusieurs Go de mémoire. Au lieu de charger l'intégralité des données on va s'appuyer sur une fonction génératrice, i.e. capable de générer à la volée un batch d'exemples sur lequel calculer une étape forward pour l'extraction des « Deep Features ».

Sur la base VOC 2007, on utilisera le générateur `PascalVOCDataGenerator` fourni : http://cedric.cnam.fr/~thomen/cours/US330X/data_gen.py. Oninstanciera le générateur sur la base d'apprentissage de la manière suivante :

```
In [ ]: !wget http://cedric.cnam.fr/~thomen/cours/US330X/data_gen.py

--2023-12-07 17:08:39-- http://cedric.cnam.fr/~thomen/cours/US330X/data_gen.py

Length: 5351 (5.2K) [text/x-python]
Saving to: 'data_gen.py'

data_gen.py          100%[=====>]    5.23K  ---KB/s    in 0s

2023-12-07 17:08:39 (582 MB/s) - 'data_gen.py' saved [5351/5351]
```

```
In [ ]: from data_gen import PascalVOCDataGenerator
data_dir = 'data/VOCdevkit/VOC2007/' # A changer avec votre chemin
data_generator_train = PascalVOCDataGenerator('trainval', data_dir)
```

Le générateur contient un dictionnaire dont les clés correspondent aux identifiants des images de la base (e.g. 000012), et les clés sont le vecteur codé au format « one-hot » (par exemple [0 1 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0]) va indiquer que l'image contient les classes bicycle et person). Un générateur va être crée par l'appel de la méthode `flow` :

```
In [ ]: batch_size = 32
generator = data_generator_train.flow(batch_size=batch_size)
```

L'appel de `next()` sur le générateur va permettre d'exécuter le code à l'intérieur de la boucle `while` de `flow`, i.e. :

- Charger en mémoire le batch d'images et de labels suivant
- Retailler chaque image en une taille précisée (224x224)
- Appliquer un pré-traitement à l'image (soustraction de l'image moyenne d'ImageNet)

Ainsi, on va pouvoir utiliser ce générateur afin d'extraire séquentiellement les données des PASCAL VOC 2007, et d'extraire les « Deep Features » :

TODO

- Utiliser ce générateur afin d'extraire séquentiellement les données de PASCAL VOC 2007
- Extraire les Deep Features de la base en train
- Répéter l'extraction sur les images de test

Pour charger la base de données PASCAL VOC2007, qui est trop grande pour être chargée en mémoire, on utilise une fonction générateur qui permet de retourner des lots d'exemples, appelée PascalVOCDataGenerator

```
In [ ]: import numpy as np
batch_size = 32
generator = data_generator_train.flow(batch_size=batch_size)
Nb_images = len(data_generator_train.images_ids_in_subset) # Nombre d'images
```

```
In [ ]: generator
```

```
Out[ ]: <generator object PascalVOCDataGenerator.flow at 0x7efd7ff3f300>
```

```
In [ ]: # Initilisation des matrices contenant Les Deep Features et Les Labels
X_train = np.zeros((Nb_images, 2048)) #2048 dim sortie du feature extractor
Y_train = np.zeros((Nb_images, 20)) #20 classes
# Calcul du nombre de batchs
nb_batches = int(len(data_generator_train.images_ids_in_subset) / batch_size) +
```

```
In [ ]: for i in range(nb_batches):
# Pour chaque batch, on extrait Les images d'entrée X et Les Labels y
X, y = next(generator)
# On récupère Les Deep Feature
z = model.predict(X)
X_train[i*batch_size:(i+1)*batch_size,:] = z
Y_train[i*batch_size:(i+1)*batch_size,:] = y

1/1 [=====] - 1s 939ms/step

```

Le temps d'extraction en CPU pour être long (plus d'une minute par batch de 32 images).
L'utilisation du GPU accélère considérablement le calcul. On calculera de manière identique la matrice des Deep Features sur la base de test. Finalement, on sauvegardera les Deep Features et labels de la manière suivante :

```
In [ ]: outfile = 'DF_ResNet50_VOC2007'
np.savez(outfile, X_train=X_train, Y_train=Y_train, X_test=X_test, Y_test=Y_test)
```

Exercice 3 : Transfert sur VOC 2007

On commencera par charger les données calculées à l'exercice précédent (téléchargeables directement ici : http://cedric.cnam.fr/~thomen/cours/US330X/DF_ResNet50_VOC2007.npz) :

```
In [ ]: outfile = 'DF_ResNet50_VOC2007.npz'
npzfile = np.load(outfile)
X_train = npzfile['X_train']
Y_train = npzfile['Y_train']
X_test = npzfile['X_test']
```

```
Y_test = npzfile['Y_test']
print("X_train=",X_train.shape, "Y_train=",Y_train.shape, " X_test=",X_test.shap
```

```
X_train= (5011, 2048) Y_train= (5011, 20) X_test= (4952, 2048) Y_train= (4952, 20)
```

On va maintenant considérer les Deep Features comme les données d'entrée et définir un réseau de neurones complètement connectés sans couche cachée pour prédire les labels de sortie.

TODO

- Créer un modèle d'une seule couche permettant la classification des features
- On prendra une fonction d'activation de type sigmoïde
- Le compiler
- L'entraîner

```
In [ ]: ##### VOTRE CODE ICI #####

Question :

Justifier le choix de la fonction d'activation de type sigmoïde par rapport à la fonction softmax habituelle.

La softmax nous donne une seule classe parmi toutes les classes, elle est exclusive. Notre problème comporte des images ou plusieurs classes peuvent être présentes, donc on veut pour chaque classe la probabilité de présence sur cette image, on utilise donc la sigmoïd ($p \approx 0$ absent, $p \approx 1$ présent).

On va maintenant compiler le modèle de la manière suivante :

Question :

Observer le code source de la fonction `binary_crossentropy` : <https://github.com/keras-team/keras/blob/master/keras/losses.py/>. Expliquer le calcul effectué dans notre cas et justifier pourquoi cette fonction de coût est adaptée au contexte multi-label.

R : La fonction de coût 'binary_crossentropy', également connue sous le nom de perte de log vraisemblance binaire, est une fonction de coût couramment utilisée pour les problèmes de classification binaire. Elle mesure la distance entre la distribution de

probabilité prédite par le modèle et la vérité terrain (les étiquettes réelles) pour chaque exemple dans l'ensemble de données.

La formule mathématique pour 'binary_crossentropy' est la suivante pour un exemple individuel :

$$L(y, \hat{y}) = -(y \cdot \log(\hat{y}) + (1 - y) \cdot \log(1 - \hat{y}))$$

- $L(y, \hat{y})$ est la perte pour un exemple individuel,
- y est l'étiquette réelle,
- \hat{y} est la probabilité prédite par le modèle.

Cette fonction de coût est adaptée aux problèmes de classification binaire car elle pénalise fortement les prédictions incorrectes. Si le modèle prédit une probabilité proche de 1 pour une classe où la vérité terrain est également 1, la perte est proche de 0. De même, si le modèle prédit une probabilité proche de 0 pour une classe où la vérité terrain est 0, la perte est également proche de 0.

Cependant, en ce qui concerne le contexte multi-label, où un exemple peut appartenir à plusieurs classes en même temps (par opposition à un seul label dans une classification binaire), 'binary_crossentropy' est toujours utilisée de manière appropriée. Chaque classe est traitée de manière indépendante, et la perte totale pour un exemple est la somme des pertes individuelles pour chaque classe.

Si un exemple appartient à plusieurs classes, la vérité terrain correspondante aura plusieurs valeurs non nulles (1 pour chaque classe à laquelle l'exemple appartient). La fonction 'binary_crossentropy' prend en compte chaque classe indépendamment, ce qui permet d'ajuster les poids du modèle pour chaque classe séparément en fonction de la pertinence de cette classe pour un exemple donné.

En résumé, 'binary_crossentropy' est adaptée au contexte multi-label car elle peut être utilisée de manière indépendante pour chaque classe, ce qui permet au modèle de s'adapter à des exemples appartenant simultanément à plusieurs classes.

On va pouvoir entraîner et évaluer le modèle classiquement :

```
In [ ]: scores = model_classif.evaluate(X_test, Y_test, verbose=0)
print("%s TEST: %.2f%%" % (model_classif.metrics_names[0], scores[0]*100))
print("%s TEST: %.2f%%" % (model_classif.metrics_names[1], scores[1]*100))
```

loss TEST: 7.98%

binary_accuracy TEST: 97.32%

Évaluation finale de performances. La métrique utilisée pour évaluer les performances sur PASCAL VOC est la Précision Moyenne (Average Precision).

TODO

- Calculer la précision pour chaque classe en utilisant la fonction `average_precision_score` de la bibliothèque Scikit-Learn

```
In [ ]: from sklearn.metrics import average_precision_score
y_pred_test = model_classif.predict(X_test)
y_pred_train = model_classif.predict(X_train)
AP_train = np.zeros(20)
AP_test = np.zeros(20)
for c in range(20):
    # Calculer la précision moyenne pour l'ensemble d'entraînement
    AP_train[c] = average_precision_score(Y_train[:, c], y_pred_train[:, c])

    # Calculer la précision moyenne pour l'ensemble de test
    AP_test[c] = average_precision_score(Y_test[:, c], y_pred_test[:, c])

print("MAP TRAIN =", AP_train.mean()*100)
print("MAP TEST =", AP_test.mean()*100)
```

```
155/155 [=====] - 0s 2ms/step
157/157 [=====] - 0s 2ms/step
MAP TRAIN = 94.34394458271471
MAP TEST = 81.92431433374013
```

conclusion

Le choix de la méthode d'apprentissage repose principalement sur deux facteurs. Le premier facteur est la taille de l'ensemble d'entraînement, et le second est la similarité de l'ensemble d'entraînement avec l'ensemble de données d'origine. Plusieurs cas se présentent :

- Si l'ensemble d'entraînement est petit et similaire à l'ensemble de données d'origine, l'apprentissage par transfert sera privilégié.
- Si l'ensemble d'entraînement est petit et ne ressemble pas à l'ensemble d'origine, entraîner uniquement la dernière couche, qui contient des caractéristiques spécifiques, ne donne pas de bons résultats. Dans ce cas, l'entraînement sur des couches plus superficielles est effectué.
- Si l'ensemble d'entraînement est grand et ne ressemble pas à l'ensemble d'origine, l'ajustement fin (fine-tuning) est le meilleur choix. L'initialisation des poids se fait à partir d'un modèle pré-entraîné.

Les caractéristiques profondes obtenues sont utilisées comme données d'entrée (de dimension 2048) pour un réseau neuronal entièrement connecté sans couches cachées. La fonction d'activation sigmoid est utilisée pour classifier les images dans 20 classes. Le choix de la fonction sigmoid s'explique par le fait que la base de données contient des images à étiquettes multiples (multi-labels) : les décisions d'attribution des classes ne doivent pas interférer entre elles. La fonction softmax ne permet pas d'atteindre cet objectif, car elle dépend de l'ensemble du vecteur de sortie, tandis que la fonction sigmoid dépend uniquement de la décision d'une classe particulière.

La cross-entropy binaire est une fonction d'activation binaire suivie d'une fonction de coût de type cross-entropy. L'utilisation d'images multi-labels nécessite une fonction de coût qui ne soit pas influencée par les décisions d'autres classes. La fonction mentionnée élimine cette influence grâce à l'introduction de la fonction sigmoid.

Les scores obtenus sont de 94 % pour l'ensemble d'entraînement et de 81 % pour l'ensemble de test. Nous avons utilisé la métrique de « précision moyenne » (average precision). Notre modèle de classification est donc assez efficace, car il gère une classification avec un nombre significatif de classes.

Exercice 4 : Fine-tuning sur VOC 2007

Enfin, on va tester un apprentissage où les paramètres du réseau seront initialisées sur la base ImageNet, mais fine-tunées sur VOC2007 pour spécialiser les représentations internes à la base cible et améliorer les performances. **N.B. : il faut impérativement utiliser une carte GPU dans cette partie.**

On commencera pour cela à charger le réseau et ajouter la couche de classification dédiée à VOC2007 :

TODO

- Retirer la dernière couche du modèle et la remplacer par une couche complètement connectée de taille adaptée

```
In [ ]: # Load ResNet50 architecture & its weights
model = ResNet50(include_top=True, weights='imagenet')
model.layers.pop()

# Modify top layers
# Add a new Dense Layer for your specific classification task
x = model.layers[-2].output
predictions_layer = Dense(20, activation='sigmoid', name='predictions')(x)

# Create a new model with the modified top layers
model = Model(inputs=model.input, outputs=predictions_layer)
```

On spécifiera ensuite qu'on souhaite apprendre les paramètres de l'ensemble du réseau :

```
In [ ]: for i in range(len(model.layers)):
        model.layers[i].trainable = True

In [ ]: from sklearn.metrics import average_precision_score
import tensorflow as tf
import numpy as np

def mean_average_precision(y_true, y_pred):
    AP = np.zeros(20)
    for c in range(20):
        AP[c] = average_precision_score(y_true[:, c], y_pred[:, c])
    return tf.reduce_mean(AP)
```

Question :

Si on avait indiqué `model.layers[i].trainable = False` pour toutes les couches sauf la dernière, dans quel mode serions-nous ?

- Si on met trainable = False, on ne veut donc pas que le gradient se rétropropage dans ces couches : c'est un freeze des paramètres du Feature Extractor, on serait dans un transfer learning sans fine tuning des paramètres

On va ensuite compiler le modèle :

```
In [ ]: lr = 0.1
model.compile(loss='binary_crossentropy', optimizer=SGD(learning_rate=lr), metri
```

Et simplement utiliser la méthode `fit_generator` pour entraîner le modèle

- `fit_generator` va prendre en paramètre la fonction `flow` qui va renvoyer un batch d'exemples et de labels. La méthode forward va comparer la sortie prédite par le modèle aux labels données par la supervision puis l'étape backward va mettre à jour l'ensemble des paramètres du modèle.

```
In [ ]: batch_size=32
nb_epochs=10
data_generator_train = PascalVOCDataGenerator('trainval', data_dir)
steps_per_epoch_train = int(len(data_generator_train.id_to_label) / batch_size)
model.fit_generator(data_generator_train.flow(batch_size=batch_size),
                    steps_per_epoch=steps_per_epoch_train,
                    epochs=nb_epochs,
                    verbose=1)
```

<ipython-input-46-a3255d9d0deb>:5: UserWarning: `Model.fit_generator` is deprecated and will be removed in a future version. Please use `Model.fit`, which supports generators.

```
model.fit_generator(data_generator_train.flow(batch_size=batch_size),
```

TODO

- Évaluer le modèle sur la base de test
- Calculer le MAP

Question :

Quel MAP obtenez-vous sur la base de test dans ce régime de fine-tuning ? Conclure.

```

In [ ]: #@title Fonction d'évaluation

def evaluate(model, subset, batch_size=default_batch_size, data_dir=default_data_dir, verbose=True):
